Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

Section 1: General description of Digitrip trip units

The Digitrip™ trip units are circuit breaker subsystems that provide the protective functions of a circuit breaker. The trip unit is in a removable sealed housing, installed in the circuit breaker, and can be replaced in the field by the end user.

This document specifically covers the application of Digitrip trip units, as illustrated in Figure 1, installed in Magnum and Magnum DS breakers. Throughout this instructional leaflet, the use of the term “Magnum Breakers” refers to both the Magnum and Magnum DS low voltage, AC power circuit breakers.

The Magnum Digitrip line of trip units consists of the model 1150 that conforms to UL® standards, and model 1150i that conforms to IEC standards. Throughout this instructional leaflet, the use of the term Digitrip 1150 trip units refers to both models unless otherwise stated.

The Digitrip 1150 trip units may be applied to either 50 or 60 Hz systems.

The Digitrip DT1150 family of trip units incorporates two microprocessors in their design. One processor is devoted totally to the task of current protection functions. This processor provides true rms current sensing for the proper coordination with the thermal characteristics of conductors and equipment. The Digitrip analyzes the secondary current signals from the circuit breaker current sensors and, when preset current levels and time delay settings are exceeded, sends an initiating trip signal to the Trip Actuator of the circuit breaker. The current sensors provide operating power to the trip unit. As current begins to flow through the circuit breaker, the sensors generate a secondary current that powers the trip unit.

The second microprocessor provides the voltage protection display, communications, metering, harmonic calculations, alarming, and auxiliary relay functions. These additional features require that auxiliary power be provided to the circuit breaker.

Figure 1. Digitrip 1150 With Rating Plug

⚠️ WARNING

DO NOT ATTEMPT TO INSTALL OR PERFORM MAINTENANCE ON EQUIPMENT WHILE IT IS ENERGIZED. DEATH OR SEVERE PERSONAL INJURY CAN RESULT FROM CONTACT WITH ENERGIZED EQUIPMENT. ALWAYS VERIFY THAT NO VOLTAGE IS PRESENT BEFORE PROCEEDING. ALWAYS FOLLOW SAFETY PROCEDURES. EATON IS NOT LIABLE FOR THE MISAPPLICATION OR MISINSTALLATION OF ITS PRODUCTS.

⚠️ WARNING

OBSERVE ALL RECOMMENDATIONS, NOTES, CAUTIONS, AND WARNINGS RELATING TO THE SAFETY OF PERSONNEL AND EQUIPMENT. OBSERVE AND COMPLY WITH ALL GENERAL AND LOCAL HEALTH AND SAFETY LAWS, CODES, AND PROCEDURES.

Note: The recommendations and information contained herein are based on experience and judgement, but should not be considered to be all-inclusive or to cover every application or circumstance that may arise.

---

① Phase protection with three trip response types (see Section 4).

② An additional setting is marked M1 where:

- Standard Circuit Breaker
  - M1 = 14 x Iₚ for Plug Amperes 200–1250A
  - M1 = 12 x Iₚ for Plug Amperes 1600, 2000, 2500A
  - M1 = 10 x Iₚ for Plug Amperes 3000, 3200A

- Double-Wide Circuit Breaker
  - M1 = 14 x Iₚ for Plug Amperes 2000, 2500A
  - M1 = 12 x Iₚ for Plug Amperes 3000, 3200, 4000, 5000A (see Section 2)
  - M1 = 10 x Iₚ for Plug Amperes 6000, 6300A

③ Only available when long time Iₚ is selected.

④ ANSI/UL versions are limited to 1200A to comply with UL and NEC® standards.

⑤ Four cause of trip LEDs indicate LONG, SHORT, INST, or GROUND trip. Making Current Release and the separate High Instantaneous Module are indicated by the Instantaneous LED.

Protection

Each Digitrip DT1150 trip unit is completely self-contained and requires no external control power to operate its basic overcurrent protection functions. It operates from current signal levels derived through current sensors mounted in the circuit breaker. The types of protection available for each model are shown in Table 1.

The Digitrip 1150 family of trip units provides five phase and two ground (time-current) curve-shaping adjustments. To satisfy the protection needs of any specific installation, the exact selection of the available protection function is adjustable. The short delay and ground fault adjustments include either a FLAT or I²t response. A pictorial representation of the applicable time-current curves for the selected protection functions is provided, for user reference, on the face of the trip unit as shown in Figure 1.

Note: The Digitrip 1150 (11LS1, 11PLSIG style) and Digitrip 1150i (11IEC, 11PIECEF) are the styles that can be used on three-pole or four-pole circuit breakers for the protection of the neutral circuit. For a three-pole circuit breaker, an external sensor of the same rating as the phase sensor needs wired to the circuit breaker. Only these styles can provide neutral protection, although all styles can provide neutral metering and alarming (one exception is that there is no metering for source or zero sequence ground fault application). These styles also have a protection setting called neutral ratio. The 100% setting is the default and is used when phase and neutral conductors are of the same ampacity. The 50% setting is for a half-sized neutral conductor and essentially shifts the long time thermal curve to the left, making it more sensitive. Refer to the National Electrical Code® (NEC) for the appropriate application for four-pole circuit breakers.

Mode of trip and status information

On all DT1150 units, a green light emitting diode (LED), labeled Status, blinks approximately once each second to indicate that the trip unit is operating normally. This Status LED will blink at a faster rate if the Digitrip is in a pickup, or overload, mode. Red LEDs on the face of the 1150 family of trip units flash to indicate the cause, or trip mode, for an automatic trip operation (for example, ground fault, overload, or short circuit trip). A battery in the Digitrip unit maintains the trip indication until the Reset button is pushed. The battery is satisfactory if its LED lights green when the Battery Test button is pushed (see Section 6).

Note: The Digitrip 1150 family provides all protection functions regardless of the status of the battery. The battery is only needed to maintain the automatic trip indication on the mimic curve of the Digitrip when auxiliary power is not available.
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

Installation and removal

Installation of the Trip Unit

Align the Digitrip unit with the molded guide ears on the platform and spring clips of the Magnum circuit breaker. Before plugging into the black edge connector, align the long pins on the bottom of the Digitrip into the white, I1, connector (see Figure 2). Press the unit into circuit breaker until the PC board edge engages into the connector and the spring clips engage over the Digitrip’s housing.

Note: Recheck visually the connector I1 to ensure all plugs are engaged properly.

Rating Plug Installation

WARNING

DO NOT ENERGIZE THE MAGNUM CIRCUIT BREAKER WITH THE DIGITRIP REMOVED OR DISCONNECTED FROM ITS CONNECTOR. DAMAGE TO INTERNAL CURRENT TRANSFORMERS MAY OCCUR DUE TO AN OPEN CIRCUIT CONDITION. THERE IS NO PROTECTION FOR THE LOAD CIRCUIT.

CAUTION

DO NOT FORCE THE RATING PLUG INTO THE CAVITY.

Use a 1/8-inch (3 mm) wide screwdriver to tighten the M4 screw and secure the plug and the trip unit to the circuit breaker (see Figure 3). Close the rating plug door.

CAUTION

THE M4 SCREW SHOULD BE TIGHTENED ONLY UNTIL IT IS SNUG. DO NOT USE A LARGE SCREWDRIVER. A 1/8-INCH (3 MM) WIDE SCREWDRIVER BLADE IS ADEQUATE.

Insert the rating plug into the cavity on the right-hand side of the trip unit. Align the three pins on the plug with the sockets in the cavity. The plug should fit with a slight insertion force.

Figure 2. Installation of the Digitrip Unit into a Magnum Circuit Breaker (Side View)

Figure 3. Installation of the Rating Plug and Mounting Screw
Trip unit/rating plug removal

To remove the rating plug from the trip unit, open the rating plug door. Use a 1/8” (3 mm) wide screwdriver to loosen the M4 screw. Pull the door to aid in releasing the rating plug from the unit.

To remove the trip unit from the circuit breaker, deflect the top and bottom spring clips to release the unit from the black mounting platform. Pull the unit to disengage the trip unit’s printed circuit board connectors J0 and I1 from the circuit breaker (see Figure 2 and Appendix C).

Wiring

The internal components of the circuit breaker and their connection points to the secondary contacts are shown in the breaker master connection diagram provided on page 42 as Appendix C.

Plexiglass cover

A clear, tamper-proof plexiglass door sits on the circuit breaker cover. This door, if sealed, allows the settings to be viewed but not changed, except by authorized personnel. The plexiglass cover meets applicable tamper-proof requirements. The cover is held in place by two cover screws. Security is ensured by the insertion of a standard meter seal through the holes in both of the cover retention screws. The plexiglass cover has an access cutout for the view functions group of pushbuttons and the Battery Test pushbutton.

Digitrip 1150 Power/Relay Module

The Power/Relay Module (see Figure 4) is a standard device for the Digitrip 1150 model. The module is installed on the molded platform under the trip unit in the Magnum circuit breaker. There are four style modules that cover the following input voltage ratings: 120 Vac, 230 Vac, 24–48 Vdc, and 125 Vdc (100–140 Vdc operating range). The burden of the Power/Relay Module is 10 VA. Check circuit breaker cover label marking for proper trip unit power and voltage rating.

Auxiliary power

When the module is wired and supplied with proper voltage, it will provide an auxiliary power supply so that the DT 1150’s (LED) display will be functional even when the circuit breaker has no load. A Digitrip 1150 unit without auxiliary power will not provide voltage, display any data, or communicate.

Alarm contacts

A second function of this module is to provide either a trip or alarm output contact via the two customer-programmed relays within the module. An assortment of relay functions can be assigned to these relays. (See the Aux. Relay programming in Appendix D and Appendix G.) Each relay is a normally open contact with a programming identification of RELAY A and RELAY C. On the Breaker Master Connection Diagram (Appendix C), these contacts are labeled ATR_Alarm and ATR_latch. The ATR_latch is a latching relay that will hold contact status even if auxiliary power is lost to the circuit breaker. This relay does require auxiliary power for resetting. The resetting of these relays requires depressing the Reset pushbutton on the front panel of the Digitrip 1150.

Ground alarm

A ground fault alarm is one of many possible programmable alarms and can provide an early warning of a ground fault condition in progress via an alarm LED.

In addition, this unit can be programmed to energize an alarm relay upon this condition. The alarm relay will reset automatically if the ground current is less than the Ground Alarm Pickup setting. On the LSIA style unit, a red Alarm Only LED (see Figure 18) will indicate the presence of ground fault current, when it is in excess of Ground Pickup setting. Ground tripping will not occur with the LSIA style unit.

Block close relay

Also in this module is a relay that can block the remote closing of a circuit breaker after a trip condition. This block function is enabled by programming the Aux Relay B via the front panel or via PowerNet™ communication (see page 59). The block close function can be further setup for AUTO or MANUAL reset via programming (11PXXX only). This trip condition requires a front panel reset to clear the block close condition.

Standards

The Digitrip 1150 Trip Units are listed by Underwriters Laboratories®, UL File E52096, for use in Magnum circuit breakers. These devices were tested to the ANSI C37.13 breaker standard and ANSI C37.17 trip unit standard. Additionally, these same units are also evaluated by the Canadian Standards Association® (CSA) under contract test report 163545.

All Digitrip units have also passed the IEC 947-2 test program that includes radiated and conducted emissions testing. As a result, all units carry the CE mark.

Figure 4. Power/Relay Module for 1150 Trip Unit
Section 2: Description of Magnum circuit breakers

General
Magnum circuit breakers are tripped automatically on overload or fault current conditions by the combined action of three components:

1. The sensors, which measure the current level and provide the energy to trip.
2. The Digitrip trip unit, which provides a tripping signal to the trip actuator when current and time delay settings are exceeded.
3. The low-energy trip actuator, which actually trips the circuit breaker.

Figure 5 shows this tripping circuit for a typical Magnum circuit breaker. This arrangement provides a very flexible system, covering a wide range of tripping characteristics described by the time-current curves referenced in Section 9.

The automatic overload and short circuit tripping characteristics for a specific circuit breaker are determined by the ratings of the installed current sensors with a matching rating plug and the selected functional protection settings. Specific setting instructions are provided in Section 4.

When the functional protection settings are exceeded, the Digitrip unit supplies a trip signal to the trip actuator. As a result, all tripping operations initiated by the protection functions of the Digitrip trip unit are performed by its internal circuitry. There is no mechanical or direct magnetic action between the primary current and the mechanical tripping parts of the circuit breaker, thus external control power is not required for overload or fault current tripping.

Low-energy trip actuator
The mechanical force required to initiate the tripping action of a Magnum circuit breaker is provided by a special low-energy trip actuator. The trip actuator is located under the black molded platform on which the Digitrip unit is supported. The trip actuator contains a permanent magnet assembly, moving and stationary core assemblies, a spring and a coil. Nominal coil resistance is 24 ohms and the black lead is positive. The circuit breaker mechanism assembly contains a mechanism-actuated reset lever and a trip lever to actuate the tripping action of the circuit breaker.

When the trip actuator is reset by the operating mechanism, the moving core assembly is held in readiness against the force of the compressed spring by the permanent magnet. When a tripping action is initiated, the low-energy trip actuator coil receives a tripping pulse from the Digitrip unit. This pulse overcomes the holding effect of the permanent magnet, and the moving core is released to trigger the tripping operation via the trip lever.

Ground fault protection
Only the Digitrip 1150 Cat. No. 11LSIG, 11PLSIG and Digitrip 1150i Cat. No. 11EC-EF, 11PIECEF provide ground fault protection.

General
When the Digitrip 1150 family includes ground fault protection features, the distribution system characteristics (for example, system grounding, number of sources, number and location of ground points, and the like) must be considered along with the manner and location in which the circuit breaker is applied to the system. These elements are discussed on page 12.

The Digitrip 1150 family uses three modes of sensing to detect ground fault currents: residual, source ground, and zero sequence (see Table 5). The breaker secondary contact inputs B-6 and B-7 are used to configure the trip unit. A jumper from B-6 to B-7 programs the trip unit for either a source ground or zero sequence configuration. Removing the jumper will program the unit for a residual ground fault scheme. This jumper resides on the stationary side of the switchgear assembly. In all three schemes, the proper current sensor input is required on the external sensor input terminals B-4, B-5 of the breaker secondary contacts.

Note: This information applies to trip units with ground.
Residual sensing—three-wire or four-wire

Residual sensing is the standard mode of ground fault sensing in Magnum circuit breakers. This mode uses one current sensor on each phase conductor and one on the neutral for a four-wire system (shown in Figure 6 and Figure 7). If the system neutral is grounded, and no phase to neutral loads are used (a three-wire system), the Digitrip 1150 with ground includes all of the components necessary for ground fault protection. This mode of sensing vectorially sums the outputs of the three individual current sensors. For separately mounted neutrals, as long as the vectorial sum is zero, then no ground fault exists. The neutral sensor (for a four-wire system) must have characteristics and a ratio that matches the three internally mounted phase current sensors. Available types of neutral sensors are shown in Figure 8. Residual ground fault sensing features are adaptable to main and feeder circuit breaker applications.

Source ground sensing

Depending upon the installation requirements, alternate ground fault sensing schemes may be dictated (see Figure 10 and Figure 11). The ground return method is usually applied when ground fault protection is desired only on the main circuit breaker in a simple radial system. This method is also applicable to double-ended systems where a midpoint grounding electrode is employed. For this mode of sensing, a single current sensor mounted on the equipment-bonding jumper directly measures the total ground current flowing in the grounding electrode conductor and all other equipment-grounding conductors.

In the CURRENT (protection) submenu, there is a setting (EXT GN D CT RATIO) that enables the presentation of ground pickup in amperes and the display of ground current in amperes when an External Ground CT is employed. This screen is presented when jumper B-6 to B-7 is present for a trip unit equipped with GROUND. External Ground CT ratios of 10, 25, 50, 100, 200, 400, 800, 1000 A:1, and “none” settings are selectable, with “none” defaulting to the plug I(T) rating. With the correct ratio selected, the GF pickup settings are adjustable in amperes.

Zero sequence sensing

Zero sequence sensing, also referred to as vectorial summation (see Figure 12), is applicable to mains, feeders, and special schemes involving zone protection. Zero sequence current transformers (5.00 x 15.38 in [128 x 390 mm] rectangular inside dimensions) are available with 100:1 (9253C07G01, G11) and 1000:1 ratios. The EXT GND CT RATIO setting described above is applicable for zero sequence.

Multiple source/multiple ground

A multiple source/multiple ground scheme is shown in Figure 13. In this figure, a ground fault is shown that has two possible return paths, via the neutral, back to its source. The three neutral sensors are interconnected to sense and detect both ground fault and neutral currents.

Ground fault settings

The adjustment of the ground fault functional settings and their effect upon the ground fault time-current curve is discussed in Section 4.

Current sensors for standard breaker

The three (three-pole) or four (four-pole) primary current sensors are located in the circuit breaker on the lower conductors of the breaker. The current sensor rating defines the circuit breaker rating (I(T)). For example, 2000A:1A sensors are used on a 2000A rated circuit breaker. There are also four auxiliary current transformers with a ratio of 10:1 that further step down the rated current to 100 milliamperes, which is equivalent to 100% (I(T)) in the Digitrip 1150.

The primary current sensors produce an output proportional to the load current and furnish the Digitrip 1150 family with the information and energy required to trip the circuit breaker when functional protection settings are exceeded.

Current sensors for double-wide circuit breakers

The six (three-pole) or eight (four-pole) current sensors installed in the circuit breaker are located on the lower conductors. The poles are paralleled and the corresponding current sensors are also paralleled (see Figure 7). For example, a 4000A circuit breaker phase rating has two 2000:1 current sensors wired in parallel, which provides an overall ratio of 4000:2. The auxiliary current transformers have a ratio of 20:1 in this size circuit breaker to further step down the full load current to 100 mA.

EATON CORPORATION www.eaton.com
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers.

Figure 9. Four-Pole 3200A Standard (4000A IEC) Circuit Breaker Using Residual Ground Fault (Earth-Fault) Sensing

Figure 10. Source Ground Fault Sensing Scheme for Standard Circuit Breaker

Figure 11. Source Ground Fault Sensing Scheme for Double-Wide Circuit Breaker

Figure 12. Zero Sequence Sensing Scheme for Standard Circuit Breaker

1. In this scheme, all breaker secondary currents (at the 100 mA level) are summed together at the PC board donut transformer to sense ground fault via element R1.
2. Do not jumper secondary contacts B-6, B-7. This will defeat all ground fault protection in application for four-pole breaker.
3. Ground fault style trip unit is installed.

1. In this scheme, the current sensors in the circuit breaker poles are parallel-wired to achieve a 4000A circuit breaker rating. The ground fault is sensed directly via element R1.
2. A jumper is required on B-6, B-7 secondary contacts to program the Digitrip 1150 to use element R1 directly for source ground sensing. If the circuit breaker is removed from the cell (B-6, B-7), jumper disconnected, Residual Ground setting will apply.
3. Source ground sensor input is via B-4, B-5. Source ground current input to secondary contacts is 2A, equivalent to one per unit ground. For example: applying a 400:1 sensor—use 800:2 ratio and use 800A value to calculate the ground pickup setting.
4. This scheme is not applicable to four-pole circuit breakers. No secondary contacts (B-4 and B-5) are available on four-pole circuit breakers. Do NOT jumper B-6, B-7 in four-pole applications.

1. This scheme uses a large zero sequence CT to magnetically sum the currents and the output is sensed via element R1.
2. A jumper is required on B-6, B-7 to program the Digitrip to use element R1. If the breaker is removed from cell (B-6, B-7) jumper disconnected, Residual Ground setting will apply.
3. The scheme is not applicable to four-pole breakers.
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

Notes:
Breaker M2 trips since this is the only breaker seeing the $I_g$ fault via element $R_5$. No jumper on B-6, B-7 terminals—all breakers are programmed for standard residual ground fault protection. AUX, CTs not shown. Wiring needed at system level is shown as a dotted line. Capital letters represent primary current. Lowercase letters represent secondary current. The three breakers (M1, M2, and T) must all have the same breaker/sensor rating.

Figure 13. Multiple Source/Multiple Ground Scheme
Section 3: Principles of operation

General
The Digitrip 1150 family of trip units is designed for industrial circuit breaker environments where the ambient temperatures can range from –20°C to +85°C, but rarely exceed 70°C to 75°C. If, however, ambient temperatures exceed this range, the trip unit performance may be degraded. In order to ensure that the tripping function is not compromised due to an overtemperature condition, the Digitrip 1150 microcomputer chips have a built-in overtemperature protection feature, factory set to trip the circuit breaker if the chip temperature is excessive. If the unit trips on overtemperature, the red Long Delay Time LED will flash and the OVER TEMP TRIP message will appear on the display.

The Digitrip uses the Eaton custom-designed CHip™, an integrated circuit that includes a microcomputer to perform its numeric and logic functions. The principles of operation of the trip unit are shown in Figure 15.

All sensing and tripping power required to operate the protection function is derived from the current sensor secondary currents whenever the circuit breaker is carrying current. These current signals develop analog voltages across the current viewing resistors. The resulting analog voltages are digitized by the CHip.

The microcomputer continually digitizes these signals. This data is used to calculate true rms current values, which are then continually compared with the protection function settings and other operating data stored in the memory. The embedded software then determines whether to initiate protection functions, including tripping the circuit breaker through the trip actuator (Ta).

Trip and operation indicators
The four Cause of Trip LEDs on the face of the trip unit, shown in Figure 1 and Figure 16 to Figure 19, flash red to indicate the reason for any automatic trip operation. Each LED is strategically located in the related segment of the time-current curve depicted on the face of the trip unit. The reason for the trip is identified by the segment of the time-current curve where the LED is illuminated. Following an automatic trip operation, the backup battery shown in Figure 15 continues to supply power to the LEDs. The LED pulse circuit, also shown in Figure 15, is provided to reduce battery burden and will flash the Trip LED approximately every four seconds. Therefore, it is important to view the unit for at least five seconds to detect a flashing trip indicator. Pushing the Reset button extinguishes the LED.

Note: A complete reset of the Digitrip 1150 requires the unit to be powered (Status LED flashing) when depressing the Reset pushbutton. Otherwise, a previous trip event may be indicated again by the LED.

Status/long pickup LED
The green Status LED will indicate the operational status of the protection CHip A microprocessor of the trip unit. Even with no external power present, if the load current through the circuit breaker exceeds approximately 12% (three-phase power) of the current sensor rating, the LED will flash on and off once each second indicating that the trip unit is energized and operating properly (see Figure 15).

In an overload (long pickup) condition this Status LED flashes at approximately four times per second while the overload persists.

Alarm LED
In addition to the green Status LED, a yellow Alarm LED is provided to indicate real-time alarm conditions existing on the power system. See Appendix D-16 for the programming of these alarms. Also, if an unusual condition is detected within the Digitrip's hardwire or firmware, this LED will light along with an alarm message.

Trip LED
The Trip LED is illuminated upon any trip condition. It is also a real-time display and incorporates the circuit breaker’s 52b auxiliary switch (also called MCR switch) input for its logic. Pushing the Reset pushbutton or closing the circuit breaker will clear this LED.

Making Current Release (MCR)
All Digitrip 1150 trip units have a making current release function. This safety feature prevents the circuit breaker from being closed and latched-in on a faulted circuit. This is a nonadjustable sensing circuit. It is preset to trip at an instantaneous current numerically equivalent to 25 x (I_n). (Note that currents of ~11 x (I_n) with maximum asymmetry also reach this threshold.)

The making current release is enabled only for the first two cycles following an initial circuit breaker closing operation. The making current release will trip the circuit breaker instantaneously and flash the Instantaneous LED as well as indicating “Making Current Trip” on the display panel.
Zone interlocking

**CAUTION**

**IF ZONE INTERLOCKING IS NOT TO BE USED AND ONLY STANDARD TIME-DELAY COORDINATION IS INTENDED, JUMPER TERMINAL B8 TO B9 ON THE CIRCUIT BREAKER SECONDARY CONNECTOR.**

Zone selective interlocking (or zone interlocking) is available on the Digitrip 1150 for the short delay and ground fault protection functions (see Figure 15). The zone interlocking signal is wired via a single set of wires labeled Zone In (Zin) and Zone Out (Zout) along with a zone common wire. The zone selective interlocking function combines the interlocking of short delay and ground fault. A Zone Out signal is issued if the ground fault pickup is exceeded or if the short delay pickup is exceeded or if the value of 2 x (I) is exceeded. Zone selective interlocking provides the fastest possible tripping for faults within the zone of protection of the circuit breaker and yet also provides positive coordination among all circuit breakers in the system (mains, ties, feeders, and downstream circuit breakers) to limit a power outage to only the affected parts of the system.

When zone interlocking is employed, a fault within the zone of protection of the circuit breaker will cause the Digitrip 1150 to:

- Trip the affected circuit breaker immediately and, at the same time
- Issue a signal to upstream Digitrip units to restrain from tripping immediately. The restraining signal causes the upstream circuit breakers to follow their set coordination times, so that the service is only locally disrupted while the fault is cleared in the shortest time possible

For an example of how zone selective interlocking may be used, see Appendix A of this Instructional Leaflet.

**Note:** The provision for the zone selective interlocking function is standard on Digitrip trip units for short time and ground fault (earth fault) functions. ANSI/UL circuit breakers with Digitrip trip units require the appropriate jumper to terminal B8 and B9 to be added on the circuit breaker if zone interlocking coordination is not desired or during testing for the appropriate time delay during short time or ground fault testing. For IEC circuit breakers with Digitrip trip units, the zone interlocking function is not wired out to the circuit breaker secondaries (i.e., zone functionality is not present in secondaries B7, B8, and B9). The trip unit will always follow the programmed short time or ground time setting. This is accomplished via a wiring harness internal to the circuit breaker. For applications that require the zone interlocking function on IEC circuit breakers with Digitrips, please contact your local Eaton representative for appropriate instructions and kit to activate the zone interlocking function.
PT module

The PT (potential transformer) module (see Figure 14 and Appendix C) is internally wired in the circuit breaker to the line side circuit breaker terminals. It provides signal data to calculate voltage, power, energy, and related data. The PT module is a three-phase, three-wire input and three-wire output step-down transformer with a wye to wye hookup.

The power (and energy) metering and protection is calculated with the convention that power flow is from top to bottom through the circuit breaker. This assumes the top side conductor to be the line side. If the distribution system is such that the bottom side is the hot side, the power values will indicate reverse power. This reading can be an absolute value via programming. For circuit breakers built before July 2006, this power reading was made an absolute value by installing a jumper from B-3 to B-7 of the secondary contacts.

**CAUTION**

A DIELECTRIC DISCONNECT PLUG LOCATED ON THE LEFT SIDE OF THE CIRCUIT BREAKER IS PROVIDED WITH THIS MODULE AND IS TO BE REMOVED WHEN DIELECTRIC TESTING OF THE CIRCUIT BREAKER IS CONDUCTED. FAILURE TO REMOVE PLUG WHEN TESTING CAN RESULT IN DAMAGE TO TRIP UNIT AND PT MODULE.
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers.

Section 4: Programming/viewing
Digitrip 1150 (via front panel)

MAIN menu

Power-up sequence

When the Digitrip 1150/1150i unit is first powered-up, two different display messages are possible. If the Digitrip has been previously commissioned with customer-made settings, the display will alternate between “Customer Settings in Use” and “Eaton-Electrical DT 1150” messages. Following this, the display will enter into the MAIN menu (see page 43).

If Digitrip settings have not been saved previously, the trip unit is using the factory default values. On power-up, the Digitrip will then display “CHANGE FACTORY SETUP?” This message will stay on the screen until the user presses ESCape or the SELect pushbutton, or until an alarm or trip condition is detected.

The ESCape pushbutton action will keep the factory settings and then will enter the MAIN menu. The factory settings are listed in page 70 and are not valid for most applications. The appropriate settings need to be defined by a qualified application engineer to provide best overall protection and coordination for the power system.

A SELect pushbutton action will provide direct entry into PROGRAM SETTING menu. The first item presented is the Current CURVE type. LSIG or IEEE or (IEC) current curve types are possible selections depending on trip unit style. Pressing SELect again will select the curve presented in the window center and then step into the individual elements that need programmed. The VIEW up and down arrow selects the function while the EDIT up and down arrow changes value. After they are set, they need to be saved by depressing the Save pushbutton. The saving will place the customer settings in use. Verify the new settings. See page 57 for program curve, page 64 for saving, and page 48 for VIEW SETTING menu.

Pushbutton definition

View functions

The “View Functions” group of pushbuttons is located in the lower right-hand side of the unit and includes the View Up (up arrow), View Down (down arrow), ESCape, SELect, and Reset buttons.

View Up / View Down—View Up and View Down allow the user to scroll through any available menu or submenu in the Digitrip 1150 display.

SELect—The SELect pushbutton selects the submenu for the blinking selection located in the middle of the display.

ESCape—The ESCape pushbutton brings the user up to the previous menu in the display. Multiple ESC pushbutton operation will display MAIN menu screen.

Reset—The Reset pushbutton will reset LEDs and screen data (see Reset Sequence).

Edit values

The “Edit Values” group located in the upper left-hand corner of the Digitrip 1150 unit consists of three pushbuttons: Edit Up (indicated by an up arrow), Edit Down (down arrow), and Save. The Edit Values pushbuttons are covered by a plexiglass cover that can be sealed.

Edit Up / Edit Down—Edit Up and Edit Down allow the user to scroll up or down, respectively, through available setting values while in any PROGRAM SETTING submenu. In the TEST menu, these buttons will raise or lower the test level when performing a self test.

Save—The Save pushbutton allows the user to save a group of selected programmable settings from any submenu in the PGM SET menu. Save is also used in the TEST menu. When prompted, pressing Save will begin the selected test.

Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

Battery Test—The Battery Test pushbutton is located on the right side of the Digitrip 1150 unit, just above the rating plug door. Battery Test will light the green LED located above the pushbutton to ensure proper voltage in the battery.

Blink mode

Middle blinking—The middle display, if blinking, indicates that the menu item is selectable or that a submenu exists when a selection brings up another menu with middle text blinking.

Programming/viewing screens

The view functions control screen viewing, while edit functions apply to programming and storing settings. ALWAYS VERIFY PROGRAMMED SETTINGS BY ENTERING VIEW SETTINGS AFTER SAVING. All screens are viewable depending on the programmed settings and/or Digitrip 1150 model. In particular, the METER submenu may be programmed to include anywhere from one to 22 viewable screens when METER is selected, based on the settings chosen in the PGM SET/DISPLAY screens. Similarly, certain screens are only viewable based on availability. For example, in the PGM SET/AuxRLY menu, the selected relay determines the programmable groups displayed. See Appendix D.

Depending on the Digitrip 1150 model, certain menus or screens are not viewable or programmable. When using the LSI factory style unit, viewing and programming menu screens involving Ground or Earth settings are not accessible. When using the LSIG factory style unit, viewing and programming screens involving Neutral Protection are not displayed.

Reset pushbutton operation (after trip)

Trip events

A Reset pushbutton operation does the following after a trip:

1. Clears the cause of trip flashing LEDs (four) after a trip event
2. Clears the Trip LED
3. Clears Display data

Note: After a Trip event:
1. Observe any Trip LED flashing on mimic curve.
2. Observe message on LED display.
3. Push View Down pushbutton to observe timestamp of event and view down to observe trip current data. This data, along with timestamp, will also be stored in event log. The maximum trip current value that can be displayed is 65535A.
4. After any trip condition, the trip unit should be reset by pressing the Reset pushbutton (see Section 4 on pending alarm events).
5. Reclose circuit breaker as desired.

See page 47 for possible trip events and screen data displayed after a trip by using the View Down (down arrow) pushbutton.

Alarm events

Alarms are tracked in real-time and a Reset pushbutton may momentarily clear the alarm but the Alarm LED and alarm message will reappear if condition is still present.

The ESCape pushbutton activation will remove the alarm message from the display and return to normal menu viewing mode, but the yellow Alarm LED will remain lit, as the alarm is in the system (see page 67).

Note: A way to clear an alarm if desired, after reviewing the alarm and its associated data, is to enter the PGM SET menu followed by the ALARM submenu. The user can then revise or turn off the associated alarm set point value.

See page 47 for possible alarm events and page 67 for multiple alarm conditions.
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

Data resets in meter screen
A Reset pushbutton operation will reset data values or group of values if the Reset pushbutton is depressed when screen value is displayed (see page 44 METER menu).

Program settings PGM SET
Current curve type selection and pickup/time settings

General
Before placing any circuit breaker in operation, set each trip unit protection setting to the values specified by the engineer responsible for the installation. Each setting is programmed using the front panel pushbuttons and Save when the desired settings are selected. A few settings are interdependent (the Long PU (I) rating will indirectly affect the Short PU value). Therefore, always verify these settings after programming by entering VIEW SETTINGS menu.

The installed rating plug must match the current sensors that establish the maximum continuous current rating of the circuit breaker (I). Instantaneous and ground current settings are defined in multiples of (I).

To illustrate the effect of each protection setting, simulated time-current curves are pictured on the face of the trip unit. Should an automatic trip occur (as a result of the current exceeding the pre-selected value), the LED in the appropriate segment of the simulated time-current curve will flash red, indicating the reason for the trip.

All Digitrip 1150 and Digitrip 1150i offer the LSIG curve as the standard factory default. The five-segment straight line curve of Long PU and Time, Short PU and Time, and Instantaneous PU are depicted on the nameplate of the product. The GROUND (EARTH) element is shown also on styles with ground fault protection. The LSIA style has ground alarm only function (see page 56 and page 57).

A second curve selection is also possible for UL/ANSI styles. An IEEE curve that accurately follows the Inverse-Time characteristic equations can be selected (IEEE draft PC37.112-1195). Curve shapes of Moderately Inverse, Very Inverse or Extremely Inverse are available under PHASE SLOPE. Each of these curve shapes have a PICKUP and TimeDIAL selection to position the curve. The short delay function is included as part of IEEE curve.

For the Digitrip 1150i, a second curve type is also possible for the international styles. An IEC curve type that accurately follows the IEC255 curve equations can be selected. The curve shapes of IEC-A (normal inverse), IEC-B (very inverse), and IEC-C (extremely inverse) are available under PHASE SLOPE. Each of these curve shapes have a PICKUP and TimeDIAL selection to position the curve. The short delay function is included as part of IEC curve.

The available settings, for the LSIG standard curve along with the effects of changing the settings, are described below and in Figure 23 through Figure 30. Sample settings are represented in boxes (e.g. [ ]).

LONG SLOPE setting
There is an I't or I't curve shape selection possible for LONG SLOPE.

LONG PU setting
There are 13 available long delay settings as illustrated in Figure 23. Each setting, called (I), is expressed as a multiple (ranging from 0.4 to 1.0) of the current (I).

Note: (I) is also the basis for the short delay current setting (see Section 4).

Figure 23. Long PU Settings

LongTIME setting
There are 45 available Long Delay Time settings I't, as illustrated in Figure 24, ranging from 2 to 24 seconds. For the I't slope, there are nine settings ranging from 1 to 5 seconds. These settings represent the total clearing times when the current value equals six times (I).

Figure 24. Long Delay Time Settings

Note: In addition to the standard Long Delay Protection element, the Digitrip 1150 trip units using LONG SLOPE settings of I't or I't also have a Long Time Memory (LTM) function, which protects load circuits from the effects of repeated overload conditions. If a circuit breaker is closed soon after a long delay trip, and the current again exceeds the long delay setting, (I), the LTM automatically reduces the time to trip to allow for the fact that the load circuit temperature is already higher than normal because of the prior overload condition. Each time the overload condition is repeated, the LTM causes the circuit breaker to trip in a progressively shorter time. When the load current returns to normal, the LTM begins to reset; after about ten minutes it will have reset fully, so the next long delay trip time will again correspond to the setting value.

Note: In certain applications and field testing, it may be desirable to disable the LTM function by disabling this function in program settings.

The action of the LTM must be considered when performing multiple long delay time tests (see Section 5).
SHORT PU setting

There are at least 19 available short delay current settings, as illustrated in Figure 25. Eighteen settings are in the range from 1.5 to 10 times ($I_r$). **REMEMBER:** ($I_r$) is the long PU current setting. The maximum value M1 depends on the sensor rating of the circuit breaker and is listed in Note 3 of Table 1.

![Figure 25. Short Delay Current Settings](image)

SHORT TIME setting

As illustrated in Figure 26, there are two different short delay slopes: fixed and $I^t$. The shape selected depends on the type of selective coordination chosen. The $I^t$ response curve will provide a longer time delay for current below $8 \times I_r$ than will the FLAT response curve.

**Note:** The $I^t$ response for short time is not available if long time is set for $I^t$, IEEE, or IEC curve.

Nine FLAT and nine $I^t$ response time delay settings are available. The $I^t$ response is applicable to currents less than eight times the ampere rating of the installed rating plug ($I_n$). For currents greater than $8 \times I_r$, the $I^t$ response reverts to the FLAT response.

**Note:** Also see Section 3, zone interlocking.

INST PU setting

There are at least 18 available instantaneous current settings, as illustrated in Figure 27. The value that M1 has depends upon the sensor rating of the circuit breaker and is specified both on the rating plug label and on the applicable time-current curves referenced in Section 9. The instantaneous pickup is based on the plug ($I_n$) rating.

GND PU setting

The ground fault current settings are labeled with values from 0.24 to 1.0 x ($I_n$) in 0.01 increments (see Figure 28). The ANSI/UL models are limited to 1200A, as shown in Table 1. The IEC-EF model earth pickup range is 0.10 to 1.0 x ($I_n$) with no 1200A limitation. External control power is required to ensure earth fault tripping for fault currents and earth fault setting less than 0.24 per unit.

![Figure 26. Short Time Settings](image)

**Amp unbalance, phase loss**

**Amp unbalance**

The amp unbalance trip function can be selected in the program settings—PROGRAM CURVE menu (see page 56). It is set to OFF as a factory default. The pickup unbalance is adjustable from 5–25%. Once selected, an associated time delay is adjustable from 0 to 240 seconds with initial factory default of 10 seconds. The setting time tolerance is ±3% or ±0.3s (whichever is greater). A difference between maximum phase and minimum phase higher than the amp unbalance percent settings will cause the breaker to trip with an AMPERES OUT OF BALANCE message and red trip LED illuminated in the right corner of the Digitrip front panel. This function does require external auxiliary power to the Digitrip unit. To avoid unnecessary operation of this function, the circuit breaker must be carrying 55% of the I<sub>r</sub> rating on at least one phase before it will trip via amp unbalance.

**Phase loss (current based)**

The phase loss trip function can be selected in the program settings—PROGRAM CURVE menu (see page 56). It is set to OFF initially as a factory default. A time delay of 1 to 30 seconds can be selected. If there exists a 75% difference between the maximum phase and minimum phase currents and if maintained for the selected time delay, the breaker will trip with a PHASE LOSS TRIP message and red Trip LED illuminated in the right corner of the Digitrip front panel. This function does require auxiliary power to the Digitrip unit. To avoid unnecessary operation of this function, the circuit breaker must be carrying 55% of the I<sub>r</sub> rating on at least one phase before it will trip via phase loss.

**Voltage—frequency, reverse power**

Refer to Table 4 for a tabulation of functions available versus the catalog number. Voltage and frequency and reverse power tripping and/or alarming can be set by entering the VOLTAGE menu under the program setting MAIN menu. Please refer to page 68 for the trip settings available and page 60 for the alarm settings available. The alarms can be mapped to Relay A and the trips to Relay B and Relay C for desired relay contact action.

The voltage function (frequency and reverse power included) has a master switch “voltage setting” (enabled/disabled) that can toggle all voltage related trip and alarm settings. The individual selections can, in addition, be enabled or disabled as desired.

**Note:** When programming the voltage or frequency setting for trip or alarm, there exists a setting interdependency feature that prevents the user from making an “over-lapping” under and over value combination. When this condition is encountered, change the value or disable the “opposite” setting temporarily to achieve the desired setting.

**Voltage, frequency protection**

These functions, unlike the LSIG current protection functions, do require a reliable source of auxiliary power available on circuit breaker secondary contacts A-14, A-15. If the circuit breaker is equipped with the 24–48 Vdc Power/Relay Module, the (+) voltage input is terminal A-14. Refer to the breaker information label for proper trip unit power voltage and see also Section 1 and Appendix C.

The voltage is sensed on all three phases. Any phase-to-phase voltage exceeding the specified setting will activate the protection function. The voltage sensing points are the main conductors at the top of the circuit breaker. This is the factory wired setup. A factory option does exist to enable bottom end of circuit breaker sensing of voltage.

**Note:** Frequency is sensed on phase A voltage input. The frequency trip, voltage trip, or alarm function will not be active if this voltage falls below 84V phase to phase.
**Voltage, frequency trip**

Voltage and frequency protection trip functions, if enabled, are active whenever the circuit breaker is closed. These trip functions are made inactive after a trip or when the circuit breaker opens. The function will be rearmed when the circuit breaker is reclosed. Observe the cause of trip message after a trip event, then reset the Digitrip by depressing the Reset pushbutton. At this time, observe the real-time data of the parameter that initiated the trip to see if it is still beyond the specified limit. Voltage and frequency data in the METER menu is real-time data independent of whether the circuit breaker is open or closed. Enter the EVENTLOG menu and observe the event that initiated the trip. When the parameter returns to within its limits, reclose the circuit breaker if desired.

**Voltage, frequency alarms**

These alarms can be enabled by the user by entering the program settings and then the ALARMS submenu. Alarms are real-time and are active when the circuit breaker is in either the Open or Closed state. If both a UV alarm and UV trip are enabled (for example), the UV trips in some scenarios. They are not totally independent. When tripped, a pushbutton Reset or Communication Reset will re-enable the UV alarm if voltage has not yet returned. The Alarm LED will light to indicate an alarm condition.

**Note:** If an underfrequency or overfrequency trip or alarm is enabled, the following restriction applies: Trip units used on 50 Hz systems have valid frequency sensing range of 43 to 59 Hz. Trip units used on 60 Hz systems have a valid frequency sensing range of 51 to 70 Hz. All trip units leave the factory set for 60 Hz. For frequencies outside the applicable range, the unit will display the alarm message “FREQ OUT OF BOUNDS.”

This alarm message also can occur if the system frequency set point does not match the nominal power system frequency. If this message is encountered, check or change the frequency setting in the SYSTEM menu. The FREQ display screen in the METER submenu will display dashes, “- - - - -”, instead of a numerical frequency.

The circuit breaker will not initiate a frequency related trip when programmed to provide frequency tripping for frequencies out of bounds. However, the alarm relay Relay A, if programmed for frequency alarming, will operate during an out of bounds condition as well as within the valid frequency range of operation.

The setting range for underfrequency or overfrequency tripping and alarming is 48.0 to 52.0 Hz for a 50 Hz system and 58.0 to 62.0 Hz for a 60 Hz system.

**Table 6** includes two examples of the circuit breaker and Relay A operation.

Voltage unbalance is adjustable from 5–50% in steps of 1%. A difference between maximum phase and minimum phase higher than the voltage unbalance setting, times minimum phase voltage, will activate the function.

**Table 6. Examples of the Circuit Breaker and Relay A Operation Versus Frequency**

Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

**Voltage, frequency relays A,B,C**

Relay A, a normally open contact, can be mapped to an alarm condition, which can provide a real-time contact information of these parameters: undervoltage, overvoltage, underfrequency, overfrequency, and voltage unbalance. Each alarm setting does have a separate time delay adjustment.

The Phase Rotation alarm can be set to ABC or CBA or OFF in the ALARM menu (see page 60). This setting if encountered in application will generate an alarm condition. Phase rotation alarm can then be mapped to this Relay A. With this contact, an interposing relay with time delay can be employed to provide time delay and contact arrangements to interface with the circuit breaker’s closing circuit (spring release coil) to either prevent closing or to open the circuit breaker (shunt trip coil). Relay B and Relay C can also be mapped to the voltage or frequency TRIP. These include undervoltage, overvoltage, underfrequency, overfrequency, and voltage unbalance trip and reverse power trip. In addition, Relay B and Relay C together will share a manual or auto reset selection. This is provided in the SYSTEM menu and will provide means to reset the Relay B and Relay C associated contacts. The Default setting is MANUAL reset. The resetting of these is accomplished via the Reset pushbutton. The AUTO Reset setting will automatically reset these two relays within five seconds after the trip event.

The phase rotation setting should be programmed in the ALARM menu to alarm when the Digitrip encounters this Phase Rotation setting.

**INCOM**

INCOM programming (see page 55) allows for five different setting options. These include address (001—FFE in hexadecimal form), baud rate (9600 or 1200), and enabling or disabling external communications trip (EXT COMM OpenTrip) and external communications close (EXT COMM CLOSE). The latter two settings will allow or disallow remote control of the circuit breaker via the computer.

The fifth setting is the DT 910 COMM mode. When enabled, the trip unit will adopt the Digitrip 910 communications protocol. This means that while the trip unit continues to execute all Digitrip 1150 functionality, the unit only transmits those messages pertaining to the Digitrip 910 and will be identified as a 910 unit to a communicating master device.

**Assemblies Electronic Monitor (AEM II) and Breaker Interface Monitor (BIM) and BIM II**

An Assemblies Electronic Monitor (AEM II) can be applied in the same assembly with the circuit breakers or at a location remote from the circuit breakers to monitor the information from any of the Digitrip 1150 trip units. The connections in the network are made by twisted pairs of wires. The AEM must use the Digitrip 910 communication setting. Its valid addresses are 001–050 decimal.

The Breaker Interface Monitor (BIM) can also be used to monitor the Digitrip 1150 trip unit. However, with BIM must also use “Digitrip 910” setting of the Digitrip 1150 product.

The above two devices mentioned can receive minimum communication from the Digitrip 1150 when set in the DT 910 mode and is not recommended for new installations. The BIM II is the preferred monitoring device to be used with the Digitrip 1150. Its range of acceptable addresses are 001–032 hexadecimal.

**Remote master computer and BIM II**

When desired, Digitrip 1150 trip units can communicate with both a Breaker Interface Monitor (BIM II) and a remote master computer (IBM PC compatible with Eaton CONI card or MINT) (see Figure 30).

**INCOM network interconnections**

INCOM sends bursts of data on a 92–115.2 kHz carrier at rates up to 9600 baud over twisted pair conductors to interconnect the many devices comprising the network.

The Digitrip 1150 will light the red LED shown in Figure 1 when transmitting on INCOM.

**Recommended cable specifications:**

- Eaton cable catalog #IMPCABLE, Style #2A95705G01
- Belden 9463 cable family
- Identical Commscope or Quabbin cables

These bursts of data can be captured and used in a variety of ways depending upon the manner in which the master computer software program is written. For example, all the settings (protection and alarm) can be programmed and viewed via the master computer. Another example is that the data for the individual phase current values are available on the network, but the software must select the appropriate data, decode it and display it in a useful manner. Following an overcurrent trip operation, the sequence of coded data varies slightly. The cause of trip and the value and phase (or ground) current responsible for the trip are available on the network.

**Auxiliary relay**

The programmable auxiliary relays in the Digitrip 1150 consist of Relay A (alarming and tripping), Relay B (block close function), and Relay C (latch relay). If at least one relay function is enabled, an asterisk will appear beside the relay letter in the menu. More than one relay function can be assigned to a physical relay except for the pulse initiator selection. The selection of Relay A, B, or C results in further selection of three “groups” of settings. Relay A, when selected, gives the option to enable or disable the pulse initiator and selectable pulse initiators. The selection of Relay A, B, or C can also be mapped to the voltage or frequency TRIP. These include undervoltage, overvoltage, underfrequency, overfrequency, and voltage unbalance trip.

**Alarms**

Alarm programming functions the same way as other options. Many alarm settings exist. A listing of these options and their settings can be found in page 60.

The selection of ALARM TO EventLOG setting will enable both alarm events as well as trip events to be time-stamped and placed in the three-position EventLOG.
Digital Relay Accessory Module

A Digital Relay Accessory Module is a separate device that is programmed via the Digitrip 1150 via ACCBUS menu. Available module addresses are 1–4. Each module has four Form C relay contacts numbered one through four. Programmable relay functions (RLY FUNC) for each relay include AUX, ALRM, BELL, DEAD, WATCH, LDT, SDT, INST, GND, HLAlm, GFAlm, and OFF. (See Appendix F for definitions of these settings.) These options may be saved for any combination of relay functions and addresses. The Digitrip 1150 acts as a master to its accessory bus network and will light a green LED located in the upper right corner of the trip unit when transmitting (see Figure 1 and also Appendix H).

The AUX function can be used as a circuit breaker auxiliary switch in application. BELL will initiate on any “protection” trip and can be used as a circuit breaker bell alarm trip function. The INST function will drive the accessory relay when an instantaneous trip is encountered. Similarly, LDT function will drive the relay on a circuit breaker Long Time trip and SDT for a short time trip. The GFT (ground fault) will operate the accessory relay on a ground trip. High load alarm will activate with the HLAlm setting, GFAlm is for a ground fault alarm function. ALRM (alarm) will drive the digital relay in the same way as the assignments of Relay A. The one exception is the accessory bus relay will not function as a Pulse Initiator. The WATCH (watchdog) function, when programmed, will pickup the relay if the module is communicating properly with the Digitrip 1150. It will drop out if the module is not communicating properly. This function should be assigned to the last physical module in a wiring lineup to verify the integrity of the wiring. Accessory bus is not available on PROTECT firmware version 8A.00.

The settings of INST, SDT, LDT, GND, HLAIm, GFAlm will require PROTECT firmware version 8A.05 or higher. Settings OVF/UV, O/F/UF, RevPwr will require versions PROTECT 8A.09 and DISPLAY 8B.09 or greater.

TripLink

TripLink is a means of transferring settings from one circuit breaker to another. TripLink transfers all protection settings and time and date, and the circuit breaker’s circuit data. The transfer of these settings may be useful for cloning a lineup of circuit breakers, cloning a circuit breaker’s settings for replacing the circuit breaker with its clone for maintenance purposes, or for making common settings for a test program.

All INCOM settings including INCOM ADDRESS are transferred via TripLink. An INCOM network does require a unique address so the address may later have to be changed.

The procedure requires a TripLink cable to provide communication between circuit breakers. The connector with the labeled end must be plugged into the circuit breaker that will receive the settings. This cable must be plugged into the Test Kit pins on the lower left-hand corner on both circuit breakers and both units must be powered up.
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

for the setting transfer to be successful. If power is not available, then use separate Auxiliary Power Module Cat. No. PRTAAPM and energize the unit by plugging keyed connector into upper right corner of the Digitrip 1150 (see Figure 1 and Figure 31).

Note: A TripLink cable when installed will disconnect that unit from the INCOM communication network.

Figure 31. TripLink Transfer

Preliminary requirements

1. Both units must be Digitrip 1150 and both must have the same Catalog (cat.) number, plug ampere rating for a successful transfer.

Note: It is recommended that both the sending and receiving units be the same firmware revision. Three cases exist:
a. Units with revision 0 are only compatible with other revision 0 units.
b. Units with revision 9 are only compatible with other revision 9 units.
c. When transferring settings having different firmware revisions will transfer all the protection settings properly. However, the accessory bus settings should be verified.

2. To send settings, the receiving circuit breaker must be in open state and without line voltage on the circuit breaker’s main terminals.

Transfer procedure

Note: It is important to realize that the transfer must be performed from the RECEIVING circuit breaker (the circuit breaker with the white connector marked “This unit to receive setpoints”).

In the PROGRAM TRIPLINK menu, if all preliminary requirements are met, the Digitrip 1150 display on the receiving circuit breaker will read “THIS UNIT TO RECEIVE.” Otherwise, an error message will appear reading “TripLink CONFIG ERROR” and the display will return to PROGRAM SETTINGS menu.

If the circuit breakers meet the preliminary requirements, the user will be prompted to “PRESS SAVE TO LEARN.” When Save is pressed, settings will transfer and a “LOADING” message will appear on the display screen. Transfer will be confirmed if successful with a “TripLink TRANSFER COMPLETE” message. Otherwise, “TripLink TRANSFER ERROR” will appear on the display.

In the event of TripLink Configuration Error, check all preliminary requirements as well as the TripLink cable connections. Also ensure that transfer is being initiated and performed on the receiving circuit breaker.

Setting time

In the Digitrip 1150, dates are displayed in DD-MmmYY format (for example, 12 Mar 98) and time is displayed in military-style format with hours from 0–23. The first screen in PGM SET TIME is a view-only screen showing the current time setting for the unit. The View Down button changes screens to the DAY programming screen where the two-digit date can be adjusted with the Edit Up or Edit Down pushbuttons. View Down then moves through the programmable three-character MONTH abbreviation, two-digit YEAR selection, two-digit HOURS, and two-digit MINUTES that are all programmed with the Edit Up and/or Edit Down pushbuttons. Seconds are not programmable and begin at 00 when time settings are saved. Using View Up in the menu will move the user through the settings in reverse order as described above (refer to page 63).

Selecting displays

Display programming options control the screens displayed in the METER menu. Program display is located in the PGM SET DISPLAY submenu. This submenu lists 22 programmable screens. The first screen sets metering for A, B, and C phase currents. The accessible bus settings should be verified.

System settings

Frequency

This setting is to reflect the power system’s operating frequency of 50 or 60 Hz. The factory default is 60 Hz.

BC relay reset

This setting is to define the reset mode of Relay B and Relay C of the Digitrip’s Power Relay Module. The selections are AUTO or MANUAL (see Section 4).

Sliding demand

A sliding demand calculation can be chosen for either the maximum kW demand or the maximum kVa demand. If neither is required, the user can choose OFF by pressing the up/down Edit Value keys.

Waveform capture

The waveform capture function can be enabled on a 1-, 5-, or 10-minute basis. It can also be disabled by selecting OFF with the Edit Value keys. If the THD alarm setting has been enabled in the ALARMS menu, the waveform capture function will automatically be set to one minute and the waveform capture OFF setting will not be available.

View settings (VIEW SET)

The VIEW SET menu will allow the user to view all of the settings presented in the PGM SET menus with the exception of the TripLink function. The user cannot edit or change settings in these menus.

FIRMWARE menu

The FIRMWARE menu enables the user to view the version and revision of the trip unit firmware. The protection firmware is displayed as PROTECT while DISPLAY firmware can be viewed by pressing the up/down View function keys.

Figure 1
METER menu

The METER menu initially will show six screens of data via the factory display setup. They are phase current, neutral and ground currents (if supplied), phase voltages, forward power, power factor and frequency, and energy values. However, the PROGRAM DISPLAY menu can be used to present metered data relevant to a specific customer application. There are 22 data screens selectable as listed on page 45 and page 58. The demand and the average, minimum and maximum current screens alternate between the data and additional information concerning the measured parameter. The minimum and maximum phase currents are actually reset as a group (see page 45). The OP COUNT screen displays circuit breaker operation where an open/close is registered as one count. The OP COUNT can be reset also when this screen is active.

HARMONIC menu

The Digitrip 1150 HARMONIC menu provides capabilities to calculate and display the total harmonic distortion (THD) for phase currents IA, IB, and IC as well as IN if available. The term THD is used to define the amount of harmonic current that the breaker is seeing or the system is experiencing in percentage of the power frequency current. This can be useful in troubleshooting to detect individual circuit breaker current loads that could lead to system problems and early equipment failure. The equation used for calculating THD is:

$$\text{THD} = \frac{\sqrt{I_{rms}^2 - I_1^2}}{I_1} \times 100\%$$

Where I rms is the rms current of the waveform and I1 is the rms current of the fundamental frequency.

For example, the THD calculation for a load having an equal rms value of the fundamental and third harmonic current would have a THD value of 100%. This would be a large value of THD and would not be typical.

In addition to individually displaying the THD for the phase currents, the Digitrip 1150 will also display the individual harmonic currents up through the 27th harmonic.

Local operation on the Digitrip to observe this data is done using the View Down pushbutton of the Digitrip.

By selecting HARMONIC from the MAIN menu, a waveform capture event and harmonic data calculation is accomplished locally. A second way is to automatically generate waveform capture on a 1-minute, 5-minute, 10-minute, or OFF basis by selecting GENERAL in the PROGRAM SETTINGS submenu and scrolling to the WAVEFORM CAPTURE option. The third way is to remotely trigger the waveform capture via a PowerNet communication command. For these three types of captures, the Digitrip 1150 will provide per harmonic data. For trip events and alarm events, the per harmonic data by manipulating the alarm to EventLoG set point located in the ALARMS PROGRAMMING menu. The event data is stored in nonvolatile RAM and is maintained on a first-in, first-out basis. In the case where the alarm to EventLoG setting is enabled, a new alarm event will replace either historic trip or historic alarm condition stored previously (see page 45).

Event log

The Digitrip 1150 trip unit has the ability to record the cause, timestamp, and associated current or related data for a maximum of three events. An event is defined as an alarm or trip condition experienced by the circuit breaker. The user has the option to record only trip function events or to record both trip and alarm functions by manipulating the alarm to EventLoG set point located in the ALARMS PROGRAMMING menu. The event data is stored in nonvolatile RAM and is maintained on a first-in, first-out basis. In the case where the alarm to EventLoG setting is enabled, a new alarm event will replace either historic trip or historic alarm condition stored previously (see page 45).

Power and energy parameters

Power has approximately a 1-second update rate and is shown as forward or reverse power in kW units. The parameters kVA and kvar are also updated in a similar time period.Demand kW is presented as forward or reverse in kW units and is based on the last average 5-minute interval. Demand kVA is also based on the last average 5-minute interval. These parameters can be reset when this screen is in view and the Reset pushbutton action will start a new 5-minute period. Programming Alarms (kW or kVA) to exceed a threshold value will produce an alarm. A timestamp is also provided if the alarm to EventLoG setting is enabled.

Demand maximum kW and demand maximum kVA are peak values that have been encountered since the last Reset of these parameters. A pushbutton Reset or INCOM Reset will start a new 15-minute interval. As a factory default, both kW and kVA demands are set for a “fixed” 15-minute window. The update rate for the calculation is 15 minutes. A “Sliding” window calculation is a possible setting that will calculate a continuous new demand value and update the value if a new maximum is encountered every minute. This SLIDING DEMAND setting is the first item in the SYSTEM (or GENERAL) screen.

The Digitrip 1150 will display locally in kWh units of both forward and reverse energy values. An additional energy parameter is kVArh. The rollover energy value is 9,999,999 for both.

The auxiliary Relay A can be assigned to a pulse Initiator function for either kVARh or kWh. When this feature is selected, Relay A will be dedicated for pulse initiator and no other relay function is possible for Relay A (see page 59). The pulse initiator provides a contact change of state to an external counter device whenever a value is exceeded. This pulse value is based on an ANSI document and is expressed as the general equation:

$$\text{Pulse Value} = 0.000717 \times I_n \text{ (plug amperes)}$$

Power quality

The Digitrip 1150 in a Magnum circuit breaker can measure a variety of parameters relating to today’s modern power system. This data can be viewed locally or via a computer remotely in which case the data can be logged.

Power factor, THD and crest factor (CF)

The system power factor is a real-time measurement with approximately a one second update rate. The tolerance is the value ± 0.02. Maximum PF and minimum PF values are historic values that are held until reset.

Total harmonic distortion (THD) of each phase and neutral (if valid) and corresponding per harmonic data up to the 27th harmonic and crest factor are available via a waveform capture trigger. This waveform capture trigger can be done locally by selecting HARMONIC in the MAIN menu or by exceeding a THD alarm threshold programmed by the user. See Section 4.
Alarms
Alarming on low power factor can be accomplished by enabling this function in the ALARM programming screen. Any system power factor seen by the Digitrip 1150 less than the level programmed will initiate an alarm message on the 24-character display as well as illuminating the yellow LED and communicating to a host computer. The power factor calculation is valid for currents less than the Long Delay Pickup level. The auxiliary Relay A can be also assigned to the THD alarm.

The THD alarm feature is an alarm setting with a range of 10–30% THD that when exceeded will initiate waveform capture and also set the front panel Alarm LED. The THD alarm has a 1-minute update rate. The auxiliary Relay A can also be assigned to a THD alarm.

Waveform capture feature
The Digitrip 1150 can respond to a command from a remote master to perform a waveform capture of phase currents Ia, IB, and IC, as well as waveform IN (on catalog LSI) or waveform IG (on catalog LSIG employing the source ground configuration). A total of 58 data points per phase per cycle is captured and can be sent to a host computer. From this data, parameters such as THD, individual harmonics content, and waveform are fabricated.

There is a timer in the Digitrip unit that will limit the acceptance of a "WAVEFORM CAPTURE" software command to once per second. Three waveforms are held in a first in, first out manner in the Digitrip's volatile memory.

Six-cycle waveform capture on trip
On long time, short time, instantaneous, or ground fault tripping events, the Digitrip 1150 will capture the curve waveforms to a buffer. The buffer as a waveform can be displayed on the master computer using the PowerNet software screen (Ref. I.L.17384 for protocol and software commands). The six-cycle waveform capture will typically contain one cycle of pre-interruption data and five cycles of interruption and post-interruption data for analysis of the power system.

Note: The phase loss, phase unbalance, voltage and frequency trips, reverse power trips, and alarm events do not produce a waveform capture.

Note: PowerNet communications will require hardware and software specified in the Eaton PowerNet operations manual and also the Digitrip 1150 Firmware must be DISPLAY Version 8B, Version 02 or greater and PROTECT Version 8A, Revision 02 or greater (see page 48).

One-cycle waveform capture
There are two methods of obtaining a one-cycle waveform capture from the Digitrip 1150. One method is via the PowerNet software to manually request a waveform capture. The second way is to trigger a waveform capture via an Alarm condition. This is accomplished by entering the PROGRAM—ALARM screen. Enable the ALARM type of interest as well as ALARM TO EventLOG.

The one-cycle waveform capture of the currents IA, IB, IC, and IN, if applicable, can then be displayed on the master computer for analysis. IG waveform is not displayed for residual ground application (see page 60).

Health (applicable only to Digitrip 1150+ Rev. E or higher)
The HEALTH menu on the Digitrip 1150 front panel will provide information on the Magnum circuit breaker’s health as well as a history of the circuit breaker and circuit it is protecting. This data is useful for planning maintenance and inspection schedules.

The type of data includes the total number of all Instantaneous and Short Delay trips seen by the circuit breaker.

A second counter shows the number of overloads (LDT) and ground faults (GFT) encountered while in service. The OP count provides data on the number of close operations experienced by the circuit breaker. The internal test function will not increment the INST/SD or the LDT/GFT counters, however, there will be count values in these registers from the factory primary injection testing. Each of these three values can be zeroed by depressing the Reset pushbutton. These counters will roll over at a value of 255. The operation counter will roll over at 65,000.

The last time the circuit breaker was operated (open or closed or tripped) is viewable with time and date displayed. Also included is the maximum temperature in degrees centigrade as seen by the Digitrip microprocessor CHIP (for screen presentations, see page 69).

The capture of the data requires external trip unit power. This data, once captured, is stored in nonvolatile memory.

These features are available to PowerNet communications using Digitrip firmware Rev. F or higher.

Note: Rev. F firmware permits maximum temperature to be reset.
Section 5: Test procedures

General

⚠️ WARNING

DO NOT ATTEMPT TO INSTALL, TEST, OR PERFORM MAINTENANCE ON EQUIPMENT WHILE IT IS ENERGIZED. DEATH OR SEVERE PERSONAL INJURY CAN RESULT FROM CONTACT WITH ENERGIZED EQUIPMENT. DE-ENERGIZE THE CIRCUIT AND DISCONNECT THE CIRCUIT BREAKER BEFORE PERFORMING MAINTENANCE OR TESTS.

⚠️ WARNING

ANY TRIPPING OPERATION WILL CAUSE DISRUPTION OF SERVICE AND POSSIBLE PERSONAL INJURY, RESULTING IN THE UNNECESSARY SWITCHING OF CONNECTED EQUIPMENT.

⚠️ CAUTION

TESTING A CIRCUIT BREAKER WHILE IT IS IN-SERVICE AND CARRYING LOAD CURRENT IS NOT RECOMMENDED. TESTING OF A CIRCUIT BREAKER THAT RESULTS IN THE TRIPPING OF THE CIRCUIT BREAKER SHOULD BE DONE ONLY WITH THE CIRCUIT BREAKER IN THE TEST OR DISCONNECTED CELL POSITIONS OR WHILE THE CIRCUIT BREAKER IS ON A TEST BENCH.

When to test

Testing prior to startup can best be accomplished with the circuit breaker out of its cell or in the TEST, DISCONNECTED, or WITHDRAWN (or removed) cell positions.

Note: Since time-current settings are based on desired system coordination and protection schemes, the protection settings selected and preset in accordance with Section 4 should be reset to their as-found conditions if altered during any routine test sequence.

Enter the TEST menu and using the Edit Up/Down pushbuttons, set the desired test current level. A test level chosen above a setting will cause a pickup/trip condition. If a pickup is not exceeded, the unit will remain in a “testing” mode for three hours or until interrupted by a real event or user pushbutton activity. (See page 65 for pushbutton sequence to conduct the testing. Press Save twice to initiate the test.) To conduct this testing as well as viewing setting (if applicable), a small Auxiliary Power Module, Cat. No. PRTAAPM, is available for these functions. This module is an intermittent duty device that is powered via 120 Vac, 50/60 Hz and will plug into the upper right corner of the product (see Figure 1).

When performing a trip unit self test in TRIP mode, tripping of the circuit breaker and activation of the associated alarm or accessory bus relays can occur. This is important to consider before initiating a test, since a circuit breaker or relay action can initiate other equipment responses in the system even if the circuit breaker is in TRIP position of a switchgear cell. The one exception to this is the ground trip self test function of the LSIA style unit. A ground trip test will not actually trip the circuit breaker but will only provide alarm display information and alarm relay operation (if enabled).

In the NON-TRIP mode of self test, the circuit breaker trip function and any associated relay will not operate when test alarm or test trips occur. The front panel indicating LED will light as well as display alarm/trip cause and trip time information.

Self testing

Prior to any self testing, the plexiglass cover will need to be removed. The Digitrip 1150 provides means via the TEST selection in the MAIN menu to conduct phase current (PH) or ground current (GND) (if applicable) type testing in either a TRIP or NON-TRIP mode.

The self test function cannot be entered if an alarm is already present. This alarm will need to be cleared before any self testing can be conducted. The self test function will terminate if any of the following conditions occur after the start of testing:

1. Any real phase current exceeds an alarm setting
2. Any real ground current exceeds 0.1 per unit.
3. If real phase current exceeds 1 x (I) while conducting a NON-TRIP test.
4. If real phase current exceeds 0.5 x (I) while conducting a TRIP test.

Functional field testing

⚠️ CAUTION

PERFORMING TESTS WITHOUT THE EATON APPROVED TEST KIT MAY DAMAGE THE DIGITRIP UNIT.

Use the test receptacle to verify a functional load test of a major portion of the electronic circuitry of the Digitrip and the mechanical trip assembly of the circuit breaker. The testing can determine the accuracy of the desired trip settings by performing Long Delay, Short Delay, and Ground Fault functional tests. The Eaton approved test kit is listed below.

<table>
<thead>
<tr>
<th>Model</th>
<th>Test Kit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digitrip 1150</td>
<td>(140D481G02R, 140D481G02RR, 140D481G03, or G04) with test kit adapter 8779C02G04</td>
</tr>
</tbody>
</table>

The test port is located on the front left-hand corner of the DT1150 units (see Figure 1). To access the port, remove the plexiglass cover from the front of the circuit breaker. Using a small screwdriver, gently pry up on the test port cover to remove this item.

The test kit authorized by Eaton for use with the Digitrip units plugs into the test port of the unit and provides a secondary injection test that simulates currents from the current transformers. Existing test kits, styles 140D481G02R, 140D481G02RR, 140D481G03 or G04, along with the Magnum test kit adapter 8779C02G04, can be used to test the trip unit and circuit breaker.

Performance testing for ground fault trip units

Code requirements

The NEC, under Article 230-95-C, requires that any ground fault protection system be performance tested when first installed. Conduct tests in accordance with the approved instructions provided with the equipment. Make a written record of this test and make the results available to the authority having inspection jurisdiction.
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

Verify the grounding points of the system using high voltage testers and resistance bridges to ensure that ground paths do not exist that could bypass the sensors.

Use a low voltage (0–24V), high-current, AC source to apply a test current of 125% of the Digitrip unit ground pickup setting through one phase of the circuit breaker. This should cause the circuit breaker to trip in less than 1 second and operate the alarm indicator. Reset the Digitrip and then reclose the circuit breaker. Repeat the test on the other two phases (see Figure 33).

Apply the same current as described above through one phase of the circuit breaker, returning through the neutral sensor. The circuit breaker should not trip, and the alarm indicator should not operate. Repeat the test on the other two phases.

---

**WARNING**

Personal injury can occur when working on power systems. Always turn off power supplying circuit breaker before conducting tests. Test out of the cell, if possible. There is a hazard of electrical shock or burn whenever working in or around electrical equipment.

---

**Figure 32. Auxiliary Power Module (Front and Back Views)**

**Standard requirements**

As a follow-up to the basic performance requirements stipulated by the NEC, UL Standard No. 1053 requires that certain minimum instructions must accompany each ground fault protection system. These statements (Section 5), plus a copy of the record forms (Figure 37, Figure 38, and Figure 39), are included as part of this instructional leaflet.

**General test instructions**

The interconnected system must be evaluated only by qualified personnel and in accordance with the equipment assembler’s detailed instructions.

To avoid improper operations following apparently correct simulated test operations, the polarity of the neutral sensor connections (if used) must agree with the equipment assembler’s detailed instructions. Where a question exists, consult the specifying engineer and/or equipment assembler.

---

**Figure 33. Connection Details for Conducting Single-Pole, Single-Phase Current Tests with the Circuit Breaker Removed from the Cell**

Apply the same current as described above through any two phases of the circuit breaker. The circuit breaker should not trip. Repeat the test using the other two combinations of circuit breaker phases (see Figure 34).

---

**Figure 34. Connection Details for Conducting Single-Phase Current Tests with the Circuit Breaker Removed from the Cell**

---

Suitable Conductors

Primary Disconnect Stabs When Drawout

Low Voltage AC Current Source

Polarity and Indentification

Shorting Conductors
An alternative test setup is shown in Figure 35. This three-pole hookup should be employed when a low ground pickup setting is to be tested like 0.24x and 0.3x and without auxiliary power present. The test circuit does provide a net residual ground current excitation of “1.” Two of the phases cancel each other out as far as ground fault but now the Digitrip is provided with three-pole power-up current simulating three-phase power.

### Section 6: Battery

#### General
The battery plays no part in the protection function of the trip unit. As indicated in Figure 15, the battery is provided to flash and power the red LED indication on the mimic curve. The battery is located under the rating plug door. A Battery Test pushbutton and a green Battery Test LED are also provided.

A second function of the battery is to provide backup power for the clock chip in the unit. The clock is used to timestamp trip and alarm events.

On initial installation of the circuit breaker, pull out the insulating tab with a quick pull (see Figure 36). This will activate the battery. Check the battery status using the Battery Test pushbutton.

#### Battery test
The battery is a long-life, lithium, camera-type unit. Check the status of the battery at any time by pressing the Battery Test pushbutton and observing the green LED. If the Battery Test LED does not light green, replace the battery. The condition of the battery has no effect on the protection function of the trip unit. Even with the battery removed, the unit will still trip the circuit breaker in accordance with its settings. However, without the battery, the Cause of Trip LED will not be lighted red if auxiliary power is lost to the Digitrip. If the battery is replaced, one or more of the Cause of Trip LEDs may be illuminated. Push the red Reset/Battery Test button to turn off the indicators; the trip unit will be ready to indicate the next cause of trip.

#### Battery installation and removal
The 3V lithium cell battery (see Figure 36) is easily removed and replaced. The battery is located in the cavity adjacent to the rating plug mounting screw, but is not part of the rating plug. Insert a small screwdriver at the left side of the rating plug, and to the left of the word OPEN, to open the rating plug door. Remove the old battery by pulling up on the removal tab that wraps under the battery cell. When inserting the new cell, pay special attention to ensure that the proper polarity is observed. The main body of the battery is the positive (+) side.

---

**Note:** The battery can be replaced at any time, even while the circuit breaker is in-service, without affecting the operation of the circuit breaker or its protection functions.
Digitrip models 1150, 1150i, 1150+, and 1150+ trip units for use only in Magnum and Magnum DS circuit breakers

**CAUTION**

**Exercise Care When Replacing the Battery to Ensure That the Correct Polarities Are Observed. Polarity Markings Are Shown on the Rating Plug When the Hinged Cover Is Open. Accidentally installing the battery in the reverse direction will not harm either the trip unit or the battery, but will defeat the function of the battery.**

The replacement battery should be the same type as that already in the trip unit or an equivalent. Acceptable 3V lithium batteries may be obtained from the following companies:

</tr>
</tbody>
</table>

![Diagram](image)

After replacing battery, properly dispose.

---

**Section 7: Frame ratings (sensor ratings and rating plugs)**

The frame rating of a circuit breaker is the maximum rms current it can continuously carry. The maximum short-circuit current rating of the circuit breaker is usually related to the frame rating as well. A current value, \(I_{n}\), that is less than the full frame rating may be chosen to be the basis for the coordination of the protection function of the circuit breaker without affecting its short-circuit current capability. For the Digitrip 1150, this is implemented by changing the current sensors and the corresponding rating plug. These sensors and rating plugs are available in kit form.

The current sensor rating is the maximum current the circuit breaker can carry with the specified current sensors installed. The sensor rating can be the same or less than the frame rating, but not greater.

This value, \(I_{n}\), is the basis for the trip unit current settings:

1. The Instantaneous and Ground current settings (if provided) are multiples of \(I_{n}\) (see Section 4).
2. The Long Delay Current setting, \(I_{L}\), is a fractional multiple of \(I_{n}\):
   \[
   \text{Long Delay Current setting} = I_{L} = LD \times I_{n} \quad \text{(see Section 4)}
   \]
3. The Short Delay Current setting is a multiple of \(I_{L}\):
   \[
   \text{Short Delay Current setting} = SD \times I_{L} = SD \times [LD \times I_{n}] \quad \text{(see Section 4)}
   \]

**CAUTION**

**Before You Fit the Rating Plug Into the Trip Unit, Be Sure to Check That the Sensor Rating Matches that Printed on the Rating Plug Door. Installing a Rating Plug That Does Not Match the Sensor Rating Can Produce Serious Miscoordination and/or Failure of the Protection System.**

**Note:** Rating plugs from Digitrip models 210, 500, or 510 CANNOT be used with Digitrip 1150 units.
# Section 8: Record keeping

Use the forms shown in Figure 37 and Figure 38 for record keeping. Fill in these forms, giving the indicated reference information and initial time-current trip function settings. If desired, make a copy of the form and attach it to the interior of the circuit breaker cell door or another visible location. Figure 39 provides a place for recording test data and actual trip values.

Ideally, sheets of this type should be used and maintained by those personnel in the user’s organization that have the responsibility for protection equipment.

**Time-current curves**

The time-current curves are listed below for particular trip unit models. All protection function time-current settings should be made following the recommendations of the specifying engineer in charge of the installation.

- 70C1041 Digitrip 1150/1150i Ground (earth) trip
- 70C1043 Digitrip 1150/1150i Instantaneous trip
- 70C1034 Digitrip 1150/1150i I^2t long time trip
- 70C1035 Digitrip 1150/1150i I^4t long time trip
- 70C1038 Digitrip 1150 IEEE Moderately inverse
- 70C1039 Digitrip 1150 IEEE Very inverse
- 70C1040 Digitrip 1150 IEEE Extremely inverse
- 70C1031 Digitrip 1150/IEC-A Normal inverse
- 70C1032 Digitrip 1150/IEC-B Very inverse
- 70C1033 Digitrip 1150/IEC-C Extremely inverse
- 70C1586 Digitrip 1150/1150i Instantaneous trip (MOSX)
- 70C1498 Digitrip 1150/1150i Maintenance Mode trip

---

**Figure 39. Typical Performance Test Record Form**
Section 10: Digitrip 1150 with Maintenance Mode

**WARNING**

ONLY CERTIFIED AND COMPETENT PERSONNEL SHOULD ATTEMPT TO INSTALL OR MAINTAIN POTENTIALLY HAZARDOUS EQUIPMENT. DO NOT ATTEMPT TO INSTALL OR PERFORM MAINTENANCE ON EQUIPMENT WHILE IT IS ENERGIZED. DEATH OR SEVERE PERSONAL INJURY CAN RESULT FROM CONTACT WITH ENERGIZED EQUIPMENT. ALWAYS VERIFY THAT NO VOLTAGE IS PRESENT BEFORE PROCEEDING. ALWAYS FOLLOW SAFETY PROCEDURES. EATON IS NOT LIABLE FOR THE MISAPPLICATION OR MISINSTALLATION OF ITS PRODUCTS.

General

Per the above WARNING, it is highly recommended that maintenance be conducted on electrical equipment including circuit breakers with the system de-energized.

For situations that arise where this is not possible, the Maintenance Mode function of the Digitrip 1150ARM family (Cat. 11ARMLSI, 11ARMLSIG, 11ARMLSLA, 11ARMIEC, 11ARMIECEF) can reduce arc flash incident energy that is generated on a fault condition. This is accomplished by an analog trip circuit which, when armed, provides a fast acting response to the fault. The reduced arc condition will occur only in devices downstream of the trip unit in Maintenance Mode. This is separate from the normal system protection setting of Instantaneous. The Maintenance Mode is located in the “SYSTEM” submenu of the programmable settings menu (PGM SET). (See Appendix for screen details.)

**CAUTION**

OBSERVE ALL RECOMMENDATIONS, NOTES, CAUTIONS, AND WARNINGS RELATING TO THE SAFETY OF PERSONNEL AND EQUIPMENT. OBSERVE AND COMPLY WITH ALL GENERAL AND LOCAL HEALTH AND SAFETY LAWS, CODES, AND PROCEDURES. A FLASH HAZARD ANALYSIS SHOULD BE DONE TO DETERMINE PERSONAL PROTECTIVE EQUIPMENT REQUIREMENTS.

**Maintenance Mode settings**

The Maintenance Mode settings provide the Arc Flash Reduction setting. 2.5 x Rating Plug Value is the maximum reduction setting, which correlates to the lowest pickup value.

Available trip current of Maintenance Mode settings:
- 2.5 x Rating Plug Amperes
- 4.0 x Rating Plug Amperes
- 6.0 x Rating Plug Amperes
- 8.0 x Rating Plug Amperes
- 10.0 x Rating Plug Amperes

**Arming Maintenance Mode**

There are three ways to arm the Maintenance Mode Arc Flash Reduction setting. One method is via the local keypad located on the trip unit. The setting is located in the “SYSTEM” submenu of programmable settings (PGM SET). When the Maintenance Mode Arc Flash reduction setting is enabled, the message “Maintenance Mode Enabled” is displayed to confirm that the function is on. If any key is pressed, the Maintenance Mode message is removed and replaced by normal display messages. If no keys are pressed, the Maintenance Mode message will reappear after 10 seconds.

For the second method, a remote switch wired through the breaker secondary contacts can remotely arm the Maintenance Mode setting. A high quality, gold plated or palladium contact is required in this application. The Maintenance Mode Enabled message will verify that the function is armed. (See wiring diagram Figure 42.)

A third method to arm the Maintenance Mode setting is via a communication device. A Palm Pilot along with an IR MINT device can be employed to arm the setting. By initiating the ENABLE setting, the Maintenance Mode selection in the control screen of the Palm, Maintenance Mode is set. There is a confirmation screen that verifies the arming. A BIM (Breaker Interface Module) is another communication method to arm the setting. When Maintenance Mode setting is enabled via device communications, this setting must be disabled by device communications.

**Figure 40. Digitrip with Arcflash Reduction Maintenance System in Magnum Circuit Breaker**

**Figure 41. Digitrip 1150 with Arcflash Reduction Maintenance System**
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

Effective October 2009

Remote indicator

Circuit breakers built after July 2006 will be wired with secondary contacts A12 which is reassigned to Maintenance Mode Enable (MM_E)—(see label on secondary contacts). A normally open contact (A10, A11) is available for customer use via programming of Relay A. This contact can be used to indicate remotely that the Maintenance Mode setting is armed. Refer to diagram below for a wiring of this remote (blue light) indicator.

Choosing the reduction setting

The Arcflash Reduction Maintenance System switch has five unique settings. From the factory, the Magnum circuit breaker is shipped with the Digitrip unit set to the 2.5x setting and with its Maintenance Mode disabled. The Maintenance Mode Enabled message provides an indication that the Maintenance Mode setting is armed per one of the three methods described on page 36.

In general, the selection of one of the Reduction Settings should be determined and selected by a person who is experienced in power system analysis.

This setting choice normally does not change unless there are future system modifications that could increase or decrease fault levels at the circuit breaker location.

For time/current curve information, refer to curve #70C1498.

Tripping and testing

The Maintenance Mode function will provide fast tripping even when the regular Instantaneous is set to OFF. The Instantaneous LED position is also used to indicate a trip initiated by the Maintenance Mode setting. The Maintenance Mode Trip message will be displayed after a trip.

The Maintenance Mode setting, external wiring (if any), and tripping functionality should all be periodically verified by primary or secondary injection current testing.

![Diagram of Maintenance Mode Wiring Digitrip 1150 with Arcflash Reduction Maintenance System](image_url)

1. The Digitrip 1150 (Cat. #11ARMxxx) can locally be placed in Maintenance Mode via front panel programming of the trip unit. The function can also be armed via a remote switch as shown. In addition, the function can be activated via communications. The display will indicate “Maintenance Mode in Use” when in this special mode.
2. The recommended selector switch for this low voltage application is Eaton part number 10250T1333-2E, which includes a contact block rated for logic level and corrosive use.
3. The maximum length of this wiring to the remote Arcflash Reduction Maintenance System switch (or alternate relay contact) is 9.78 feet (3m). Use #20 AWG wire or larger.
4. Control voltage is 120 Vac or 230 Vac or 24–48 Vdc or 125 Vdc as ordered. Check Magnum circuit breaker front cover for trip unit power requirements.
5. A remote stack light, annunciator panel or other remote indication device can be connected to remotely verify that the Digitrip is in Maintenance Mode.
6. Relay A contact changes state when Digitrip is in Maintenance Mode. This action requires pre-assigning Relay A to Maintenance Mode function. Relay C contacts (A9, A10) are also available to be programmed to provide an indication of a trip in Maintenance Mode. Contact is rated 1A at 120 Vac or 0.5A at 230 Vac or 1A at 24–48 Vdc or 0.35A at 125 Vdc.
7. The Digitrip 1150 can also be placed remotely in its Maintenance Mode via a general purpose relay (ice cube type with logic level contacts) activated by a remote control switch. A recommended type is IDEC Relay Ry22. Choose voltage as desired.
Appendix A: Zone interlocking examples

⚠️ NOTICE

THE PROVISION FOR ZONE INTERLOCKING IS STANDARD ON CIRCUIT BREAKERS WITH DIGITRIP TRIP UNITS FOR SHORT TIME AND GROUND FAULT FUNCTIONS. THE APPROPRIATE JUMPER TO TERMINAL B8 AND B9 MUST BE ADDED ON THE CIRCUIT BREAKER IF ZONE INTERLOCKING IS NOT DESIRED OR IF FIELD TESTING IS DESIRED.

Note: The provision for the zone selective interlocking function is standard on Digitrip trip units for short time and ground fault (earth fault) functions. ANSI/UL circuit breakers with Digitrip trip units require the appropriate jumper to terminal B8 and B9 to be added on the circuit breaker if zone interlocking coordination is not desired or during testing for the appropriate time delay during short time or ground fault testing. For IEC circuit breakers with Digitrip trip units, the zone interlocking function is not wired out to the circuit breaker secondaries (i.e., zone functionality is not present in secondaries B7, B8, and B9). The trip unit will always follow the programmed short time or ground time setting. This is accomplished via a wiring harness internal to the circuit breaker. For applications that require the zone interlocking function on IEC circuit breakers with Digitrips, please contact your local Eaton representative for appropriate instructions and kit to activate the zone interlocking function.

Example 1: There is no zone selective interlocking. (Standard time delay coordination is used.)

Assume that a ground fault of 2000A occurs and refer to Figure 43.

Fault at location 3
The branch circuit breaker will trip, clearing the fault in 0.1 seconds.
Fault at location 2
The feeder circuit breaker will trip, clearing the fault in 0.3 seconds.
Fault at location 1
The main circuit breaker will trip, clearing the fault in 0.5 seconds.

Example 2: There is zone selective interlocking.

Assume a ground fault of 2000A occurs and refer to Figure 43.

Fault at location 3
The branch circuit breaker trip unit will initiate the trip in 0.045 seconds to clear the fault and the branch will send a restraint signal to the feeder trip unit; the feeder will send a restraint interlocking signal to Z1.
Main and feeder trip units will begin to time out and, in the event that the branch circuit breaker does not clear the fault, the feeder circuit breaker will clear the fault in 0.3 seconds (as above). Similarly, in the event that the feeder circuit breaker does not clear the fault, the main circuit breaker will clear the fault in 0.5 seconds (as above).

Fault at location 2
The feeder circuit breaker trip unit will initiate the trip in 0.045 seconds to clear the fault and will send an interlocking signal to the main trip unit. The main trip unit will begin to time out and, in the event that the feeder circuit breaker does not clear the fault, the main circuit breaker will clear the fault in 0.5 seconds (as above).

Fault at location 1
There are no interlocking signals. The main circuit breaker trip unit will initiate the trip in 0.045 seconds.

Figure 44 presents a zone selective interlocking connection diagram for a system with two main circuit breakers from incoming sources and a bus tie circuit breaker.

Note: The blocking diode D1 is needed so that the feeder circuit breakers can send interlocking signals to both the main and the tie circuit breakers and prevent the tie breaker from sending an interlocking signal to itself.

---

**Figure 43. Typical Zone Interlocking**

---

**Notes:**

A1: Wiring to be twisted pair of AWG #14 to #20. Route zone interlocking wiring separate from power conductors. DO NOT GROUND any zone interlocking wiring.

A2: The maximum distance between two farthest breakers on different zones (from the Zo downstream to ZI upstream terminals is 250 feet (76m).

A3: A maximum of 20 breakers may be contained in parallel in one zone.

A4: Provide a self-interlocking jumper (on Zone 3) if coordination is desired with other downstream circuit breakers not providing the zone interlock feature.

Legend:

- C = Common (ungrounded)
- Zo = Zone out output signal to higher level zone
- ZI = Zone In input signal from lower level zone
- B7—Contact
- B8—Contact
- B9—Contact
- Fault at location 2

Effective October 2009

Instructional Leaflet II70C1036H06

1150i+ trip units for use only in Magnum and Magnum DS circuit breakers

Notes:

1. Three-wire crimp if High Instantaneous Trip Module is supplied.
2. All auxiliary switch contacts shown with breaker in OPEN position and with trip unit in "non-tripped" state (OTS switches).
3. The "SR" device has additional circuitry that provides a 0.5-second signal pulse for closing operation. Power must be removed and then reapplied for a subsequent operation.
4. To provide selected time delays for short time and/or ground time functions for testing or non-zone interlocking applications, a jumper from B-8 to B-9 is required.
5. Normally open contact programmed as Relay A, via Digitrip front panel.
6. Normally open contact programmed as Relay B, via Digitrip front panel.
7. Normally open contact programmed as Relay C, via Digitrip front panel.
8. Jumpering B-3 to B-7 terminal will eliminate reverse power condition.
9. Jumpering B-3 (NoPoW) to B-7 terminal will defeat residual ground fault element (for testing purposes only).
10. Jumpering B-6 to B-7 will defeat residual ground fault element (for testing purposes only).
Appendix D: Display menu diagrams

If any current curve setting (shown on page 56 and page 57) is changed from the factory settings (page 68), the unit will display the following screens on power up.

1 Screens will alternate back and forth for 6 seconds and then fall into the MAIN menu.

Notes:
- BOLDFACE text is blinking.
- Menu screens “wrap around” when using the View buttons.
- Editable values “wrap around” when using the Edit buttons.

When a trip event occurs, data from the appropriate METER menu screens is captured and then logged for that event. The event numbering scheme is a first-in, first-out type. However, always use the Time Stamp data provided and not the Event # as a chronicle.

An alarm event will be logged if “ALARM TO EventLOG” has been ENABLED (page 60).

In cases where Trip Unit Power (aux. power) is lost during or prior to a tripping event, the Time Stamp message will display “No EventLog.”

POSSIBLE EVENTS and LOGGED METER menu screen(s) are listed on the following page.

Default time is Jan with other values set to 0.

Relays B and C only

Relay A only
Program Alarms

Notes: Front panel display of NEUTral AMPere ALARM will be in amperes. Equation used is:

\[ \text{amperes} = I_n \times \text{Neutral Alarm Pickup Setting} \times 0.10 \] where \( I_n \) is range.

The neutral alarm (if not set to OFF) will also alarm if neutral (long pickup value) is exceeded.

The neutral alarm function is not possible on breakers used in a source ground or zero sequence ground fault application.

Voltage, frequency, and phase rotation alarming requires Digitrip Cat. No. 11PXXX.

If IEC-EF style, EARTH will replace GROUND.

Using the View keys to scroll, the 1st through 27th harmonic of each line can be viewed.
If more than one alarm condition exists in the system, the Multiple Alarm screen will be displayed and alternate with one of the alarm causes. Pressing the Select pushbutton will display the next alarm condition. Pressing the Escape will exit out and return to normal menu screen. However, the Alarm LED stays on as a reminder.
Program Voltage

| Curve type                                    | The curve type:  
LSI—Long, short, instantaneous  
LSIG—Long, short, instantaneous, ground  
LSIA—Long, short, instantaneous, alarm on ground only  
IEEE—IEEE Mod. Inv., Very Inv., Extremely Inv. short, instantaneous  
IEC—(IEC-A, -B, -C) short, instantaneous |
| Rating \( I \)                               | Breaker maximum full load current continuous rating \( I \) in amperes (plug rating)                                                      |
| Frequency                                     | Measured system frequency of voltage                                                                                                     |
| Ground current sensing                        | Residual or source ground or zero sequence                                                                                               |
| Long delay pickup \( I \)                     | Defines a current level where load current above this setting will cause an eventual trip                                               |
| Rating \( I \)                                | The continuous current setting of the circuit breaker                                                                                     |
| Long delay slope                              | Shape of the inverse-time-overcurrent (long time) curve: \[ I_t \]                                                                     |
| Long delay time                               | The time delay setting in seconds before tripping at 6 x \( I \) current level                                                          |
| Short delay pickup (a multiple of \( I \))     | Defines a current setting usually set much higher than continuous current that will initiate timing of this function                    |
| Short delay slope                             | Shape of the short time curve \[ I_t \] (applicable with \( I_t \) long delay slope only)                                               |
| Short delay time                              | The delay time after short delay is picked up                                                                                           |
| Instantaneous pickup [a multiple of \( I \)]  | Current above this setting will trip the circuit breaker immediately                                                                   |
| Ground (earth) fault pickup (a multiple of \( I \)) | Ground current above this setting will initiate a ground trip or ground alarm                                                          |
| Ground (earth) slope                          | Shape of the ground curve: \[ I_t \]                                                                                                      |
| Ground (earth) time                           | The delay time before tripping on ground                                                                                                |
| Pickup                                        | Defines a current level where load current above this setting will cause an eventual trip for the IEEE or IEC curve types            |
| Rating \( I \)                                | The continuous current setting of the circuit breaker                                                                                     |
| Time dial                                     | The time dial setting controls the time scale that determines the tripping of the inverse time characteristic for an IEEE or IEC curve |
| Amperes out of balance trip % unbalance       | Percent difference setting between the maximum and minimum phase currents that, when exceeded, will trip the circuit breaker            |
| Amperes out of balance trip time              | The required duration of the Amperes Out of Balance Trip condition before the circuit breaker trips                                         |
| Phase loss trip time                          | The phase loss time is the duration of a phase loss condition before the circuit breaker trips. This function will trip when a 75% difference |
| External ground scale factor                  | User-selectable ground CT ratio (when applicable)                                                                                         |
| Neutral ratio                                 | User-selectable. 50 or 100%. Select 50% for protecting half-size neutral conductors (applicable for non-ground fault units only)       |
| 4th pole protection                           | Neutral or 4th pole protection (applicable for non-ground fault style units)                                                            |

① This relay contact is programmed via Digitrip 1150 as Relay A. See page 59.
② This relay contact is programmed via Digitrip 1150 as Relay B. Block close will prohibit the remote closing of the circuit breaker.
③ This relay contact is programmed via Digitrip 1150 as Relay C. This relay will hold contact status on loss of auxiliary power.
④ Contact rating (resistive load):
   - AC 0.5A at 230 Vac
   - AC 1A at 120 Vac
   - DC 1A at 48 Vdc
   - DC 0.35A at 125 Vdc
⑤ Verify input voltage rating before energizing circuit.

Figure 46. Auxiliary Relays
Appendix H: Digital relay accessory module

The Digitrip 1150 front panel is used to program the external module for any combination of the following: Aux Switch, BELL Alarm, INST, SDT, LDT GndT or GFAlm, HLAlm, DEADman, WATCHDOG, ALARM, (the Alarm relay tracks the function of the Aux ReLaY A programming).

Each module has four relays. Each relay has a Form C contact with each having a rating of 10A maximum at 250 Vac.

Control voltage is 120 Vac ± 20% or 48–125 Vdc.

Accessory bus modules use DIN rail mounting. Connector types are plug-in-Phoenix. Four Form C contacts use 12-pin connector part #1835193. Power is 5-pin part #1835122. Communication is 3-pin. Part #1835196.

Communication cable is Eaton style 2A957805G01 or Belden 9463 cable.

Set switch to corresponding address (001–004) programmed via the Digitrip front panel. See page 61.

Set switch up to insert 100 ohm terminating resistor on last relay of network.

Figure 47. Digital Relay Accessory Module
Appendix I: Modbus translator wiring

The Digitrip 1150 in a Magnum circuit breaker can communicate its data using Modbus RTU protocol by employing a mMINT device to act as a translator from INCOM communication to Modbus communications. A Modbus master device is shown wired to gather data and can provide control logic to open and close circuit breakers. The mMINT Module Cat. No. mMINT uses DIN rail mounting. Connector types are plug-in-Phoenix. Power is 5-pin.

INCOM network uses a 3-pin. The RS-485 Modbus uses a 4-pin connector that consists of signals A, B, COMmon, and SHielD.

Three baud rates of 1200, 9600, or 19200 are selectable via programming switch for the Modbus network. The INCOM baud rate is fixed at 9600 baud.

Figure 48. Modbus Translator Wiring

1. Control voltage is 120 Vac ± 20% or 24–125 Vdc.
2. Communication cable is Eaton style 2A857805G01 or Belden 9463 cable.
3. The overall network will support up to 32 devices with any addresses from 1–247.
4. Terminating resistor is 121 ohm 1 watt. Use the mMINT switches to insert these terminators at the mMINT device.
5. Ground cable shield at this terminal.
Digitrip models 1150, 1150i, 1150+, and 1150i+ trip units for use only in Magnum and Magnum DS circuit breakers
