Improve safety and system reliability with environmentally preferred switchgear

Eaton’s Cooper Power™ series VFI underground distribution switchgear is versatile in application while providing a safer, more reliable and environmentally preferred approach to switching and protection requirements for 15, 25 and 35 kV systems.

**Environmentally preferred**

Climate change and the ecological impact of industrial operations have increased concerns and actions of business and government. Thought leaders are using this as an opportunity to enhance their operational performance and promote responsible corporate stewardship, increasing the demand for sustainable products and solutions. Eaton has been a leader in addressing these issues by developing biodegradable liquid dielectric products for more than 25 years.

Envirotex™ FR3™ fluid is a vegetable oil–based dielectric fluid used extensively in transformer applications globally. Biodegradable E200™ is a clear, low-viscosity fluid with excellent thermal and dielectric properties across the full temperature range for switchgear. Combined with a fire point greater than 300 °C, this makes E200 fluid ideally suited for switchgear applications.

E200 fluid is the environmentally preferred choice for vacuum fault interrupter (VFI) switchgear because it eliminates the need for SF₆ gas. Identified as one of the most potent greenhouse gases by the United States Environmental Protection Agency, one pound of SF₆ gas has the same global warming impact as 11 tons of CO₂. Relatively low emissions of SF₆ may have a large and lasting impact.

Load and fault interruption in SF₆ also produces toxic byproducts. With VFI switchgear, all interruption takes place within sealed vacuum interrupters, independent of the dielectric medium. This eliminates the added cost and complexity of special safety regulations and protocols associated with SF₆ switching byproducts.

Eaton’s Cooper Power series VFI underground distribution switchgear helps avoid potential regulatory burdens and added life-cycle costs and is the responsible way to promote sustainable operations and a green supply chain.

**VFI vacuum fault interrupter underground distribution switchgear**

- Environmentally preferred
- E200™ fluid is the SF₆-free dielectric medium of choice
- Obsolesces potent greenhouse gas (SF₆) equipment
- Eliminates costs of compliance with increasing government regulations
- Vacuum switching never contaminates the insulating medium
- Operator safety
- 100% deadfront construction
- Visible-break and grounding switches are available options for added safety
Operator safety
The deadfront construction of VFI underground distribution switchgear provides added safety for utility and maintenance personnel. Inside, all terminations are insulated rubber connectors with surfaces at ground potential. All high-voltage bus work and internal parts are completely immersed within a sealed insulating dielectric medium. This not only provides a safer working environment, but also eliminates the contamination problems of moisture, dirt and wildlife commonly associated with air-insulated switchgear.

Available side-mounted operators eliminate the need to stand in front of equipment and limit exposure to the high-voltage compartment. Because there is no need to enter this area, routine switching can be performed without entering the high-voltage compartment. In addition, all switches, interrupters and components are hot-stick operable, increasing the distance to the high-voltage area.

The optional visible-break switch with viewing window verifies an open circuit without removing the cables. Large, easily viewed contacts show the open/close position of the visible-break switch. A switch having a cable ground position is also available. With these options, there is no doubt that a circuit is open, closed or grounded.

Improve distribution reliability
VFI switchgear solves many distribution system reliability problems. For three-phase applications that experience single-phase fuse interruptions, the three-phase ganged-trip VFI switchgear eliminates ferroresonance and motor damage due to abnormal system voltage. An overcurrent on any phase simultaneously opens all three phases and reduces the risk of damage to connected equipment from single-phasing and associated downtime. VFI units can also be specified with single-phase trip to provide individual phase protection for true single-phase loads.

The VFI interrupter mechanism allows immediate service restoration, eliminating the expense associated with stocking and changing out fuses. The VFI interrupter also serves as a vacuum load-break switch, increasing operability and saving time and money.

Our VFI control offers overcurrent protection and coordination flexibility, including multiple TCCs, variable minimum-trip settings and instantaneous trip. Options include ground sensing, minimum-response time adder and a minimum-trip multiplier to solve the most complex coordination problems.

Underground distribution system automation
VFI automation speeds service restoration, system reconfiguration, fault targeting and system monitoring through remote operation. Advanced protection, communication, metering, SCADA and automation capabilities are available with Eaton’s Smart VFI—a fully integrated, self-contained package utilizing internal sensing and control power, and Edison™ Idea™-based controls for customizable protection, SCADA and automation, and an inherently flexible upgrade path for future requirements.

Eaton’s Cooper Power series VFI switchgear has the flexibility to be supplied with advanced automation capabilities or with provisions allowing their addition at a later date.

Field-proven dependability
All internal mechanisms and bus work are insulated within a sealed tank with a choice of dielectric media, including E200. Contrasted to air-insulated units that are open to contamination, there is no requirement to regularly clean barriers, insulators or live parts—greatly decreasing maintenance costs and allowing VFI switchgear to be used in locations where air-insulated switchgear cannot, such as flood-prone areas.

Both load interruption and fault interruption take place within the sealed vacuum interrupter without arcing byproducts to contaminate the insulating medium. The vacuum interrupters do not rely on the insulation medium for proper interruption, giving the VFI switchgear more flexibility to fit any application by allowing different dielectric mediums to be used.

Advanced technology vacuum interrupters are reliable, have long life and require no maintenance. Eaton’s Cooper Power series patented design reduces the arc energy—resulting in far less contact erosion and the longest life of any vacuum interrupter in the industry.

VFI distribution switchgear is available as UL® listed and labeled, providing a cost-effective solution that will meet state and local electrical codes as applicable.
